TIMBER TOWER:
10 20 30

Mythos 10 20 30 has dealt with the subject of timber towers. I have elsewhere chosen different directions, so a further understanding in the current context.

The reason why the topic for my thesis was the need to do something before the time ran out for me. I think that the subject of timber towers touches on the two biggest problems facing our time, overconcentration and energy change.

The design of timber towers is based on a simple rectangular form on an orthogonal form. The building offers open, flexible plans and multi-functional spaces. The widespread use of glazing on the inside and the green roofs of the top and the use of natural light and heat-collecting walls in the outside, as well as the use of concrete, promotes a natural lifestyle and affect the sustainable living. Leaving the building, the form of the building is still clearly visible in the urban context.

My thesis offers an alternative to the current urban structural systems. It offers a vivid ideal case in the use of built-in structural support. The structure is designed by relying on prefabricated parts, that allow for high precision, and makes the building extremely easy to assemble and disassemble to mobile units based on a flexible grid both in the horizontal and vertical and in the choice of materials.

The architecture might seem simple, but I've worked through the ISO dynamics and several building systems to arrive at the current state of the building. It was important to me to find the right mix of different parts that would work together. The building is designed to be a simple, logical structure. The material of the building is a mixture of steel, concrete, and wood. The timber used is chosen for its high quality and durability.

The construction of the building takes place as follows: The structural elements are prefabricated and delivered to the construction site. The construction process is divided into two main parts: the structural and the architectural. The structural part includes the installation of the steel framework, the concrete slabs, and the timber elements. The architectural part includes the installation of the facade, the insulation, and the interior finishes.

The timber tower is designed to be a sustainable building. The use of timber as a building material is a great way to reduce the carbon footprint of a building. The timber used is carefully selected to ensure that it is of high quality and sustainable. The building is designed to be energy-efficient, with a high degree of insulation and airtightness. The building is also designed to be visually appealing, with a combination of materials and a modern design.

The timber tower is a unique building that demonstrates the potential of timber as a building material. The building is a testament to the ability of architects to create something new and innovative with timber.

The building is located in a populous area of the city, and it is designed to blend in with the surrounding buildings. The building is designed to be energy-efficient, with a high degree of insulation and airtightness. The building is also designed to be visually appealing, with a combination of materials and a modern design.
