Abstract. We present a new algorithm $IDS$ for incremental learning of deterministic finite automata (DFA). This algorithm is based on the concept of distinguishing sequences introduced in [Angluin 1981]. We give a rigorous proof that two versions of this learning algorithm correctly learn in the limit. Finally we present an empirical performance analysis that compares these two algorithms, focussing on learning times and different types of learning queries. We conclude that $IDS$ is an efficient algorithm for software engineering applications of automata learning, such as testing and model inference.

1 Introduction

In recent years, automata learning algorithms (aka. regular inference algorithms) have found new applications in software engineering such as formal verification (e.g. [Peled et al. 1999], [Clarke et. al. 2002], [Luecker 2006]) software testing (e.g. [Raffelt et al. 2008], [Meinke and Sindhu 2011]) and model inference (e.g. [Bohlin and Jonsson 2008]). These applications mostly centre around learning an abstraction of a complex software system which can then be statically analysed (e.g. by model checking) to determine behavioural correctness. Many of these applications can be improved by the use of learning procedures that are incremental.

An automata learning algorithm is incremental if: (i) it constructs a sequence of hypothesis automata $H_0, H_1, \ldots$ from a sequence of observations $o_0, o_1, \ldots$ about an unknown target automaton $A$, and this sequence of hypothesis automata finitely converges to $A$; and (ii) the construction of hypothesis $H_i$ can reuse aspects of the construction of the previous hypothesis $H_{i-1}$ (such as an equivalence relation on states). The notion of convergence in the limit, as a model of correct incremental learning originates in [Gold 1967].

Generally speaking, much of the literature on automata learning has focussed on offline learning from a fixed pre-existing data set describing the target automaton. Other approaches, such as [Angluin 1981] and [Angluin 1987] have considered online learning, where the data set can be extended by constructing and posing new queries. However, little attention has been paid to incremental
learning algorithms, which can be seen as a subclass of online algorithms where serial hypothesis construction using a sequence of increasing data sets is emphasized. The much smaller collection of known incremental algorithms includes the RPNI2 algorithm of [Dupont 1996], the IID algorithm of [Parekh et al. 1998] and the algorithm of [Porat, Feldman 1991]. However, the motivation for incremental learning from a software engineering perspective is strong, and can be summarised as follows:

(1) to analyse a large software system it may not be feasible (or even necessary) to learn the entire automaton model, and

(2) the choice of each relevant observation $o_i$ about a large unknown software system often needs to be iteratively guided by analysis of the previous hypothesis model $H_{i-1}$ for efficiency reasons.

Our research into efficient learning-based testing (LBT) for software systems (see e.g. [Meinke 2004], [Meinke, Niu 2010], [Meinke and Sindhu 2011]) has led us to investigate the use of distinguishing sequences to design incremental learning algorithms for DFA. Distinguishing sequences offer a rather minimal and flexible way to construct a state space partition, and hence a quotient automaton that represents a hypothesis $H$ about the target DFA to be learned. Distinguishing sequences were first applied to derive the ID online learning algorithm for DFA in [Angluin 1981].

In this paper, we present a new algorithm incremental distinguishing sequences (IDS), which uses the distinguishing sequence technique for incremental learning of DFA. In [Meinke and Sindhu 2011] this algorithm has been successfully applied to learning based testing of reactive systems with demonstrated error discovery rates up to 4000 times faster than using non-incremental learning. Since little seems to have been published about the empirical performance of incremental learning algorithms, we consider this question too.

The structure of the paper is as follows. In Section 2, we review some essential mathematical preliminaries, including a presentation of Angluin’s original ID algorithm, which is necessary to understand the correctness proof for IDS. In Section 3, we present two different versions of the IDS algorithm and prove their correctness. These are called: (1) prefix free IDS, and (2) prefix closed IDS. In Section 4, we compare the empirical performance of our two IDS algorithms with each other. Finally, in Section 5, we present some conclusions and discuss future directions for research.

1.1 Related Work

Distinguishing sequences were first applied to derive the ID online learning algorithm for DFA in [Angluin 1981]. The ID algorithm is not incremental, since only a single hypothesis automaton is ever produced. Later an incremental version IID of this algorithm was presented in [Parekh et al. 1998]. Like the IID algorithm, our IDS algorithm is incremental. However in contrast with IID, the IDS algorithm, and its proof of correctness are much simpler, and some technical errors in [Parekh et al. 1998] are also overcome.
Distinguishing sequences can be contrasted with the complete consistent table approach to partition construction as represented by the well known online learning algorithm L* of [Angluin 1987]. Unlike L*, distinguishing sequences dispose of the need for an equivalence oracle during learning. Instead, we can assume that the observation set P contains a live complete set of input strings (see Section 2.2 below for a technical definition). Furthermore, unlike L*, distinguishing sequences do not require a complete table of queries before building the partition relation. In the context of software testing, both of these differences result in a much more efficient learning algorithm. In particular there is greater scope for using online queries that have been generated by other means (such as model checking). Moreover, since LBT is a black-box approach to software testing, then the use of an equivalence oracle contradicts the black-box methodology.

In [Dupont 1996], an incremental version RPNI2 of the RPNI offline learning algorithm of [Oncina and Garcia 1992] and [Lang 1992] is presented. The RPNI2 algorithm is much more complex than IDS. It includes a recursive depth first search of a lexicographically ordered state set with backtracking, and computation of a non-deterministic hypothesis automaton that is subsequently rendered deterministic. These operations have no counterpart in IDS. Thus IDS is easier to verify and can be quickly and easily implemented in practice.

The incremental learning algorithm introduced in [Porat, Feldman 1991] requires a lexicographic ordering on the presentation of online queries, which is less flexible than IDS, and indeed inappropriate for software engineering applications.

2 Preliminaries

2.1 Notation and Concepts for DFA

Let Σ be any set of symbols then Σ* denotes the set of all finite strings over Σ including the empty string λ. The length of a string α ∈ Σ* is denoted by |α| and |λ| = 0. For strings α, β ∈ Σ*, αβ denotes their concatenation.

For α, β, γ ∈ Σ*, if α = βγ then β is termed a prefix of α and γ is termed a suffix of α. We let Pref(α) denote the prefix closure of α, i.e. the set of all prefixes of α. We can also apply prefix closure pointwise to any set of strings. The set difference operation between two sets U, V, denoted by U \ V, is the set of all elements of U which are not members of V. The symmetric difference operation on pairs of sets is defined by U ⊕ V = (U \ V) ∪ (V \ U).

A deterministic finite automaton (DFA) is a quintuple A =< Σ, Q, F, q₀, δ > where: Σ is the input alphabet, Q is the state set, F ⊆ Q is the accepting state set and q₀ ∈ Q is the starting state. The state transition function δ of A is a mapping δ : Q × Σ → Q, and δ(qᵢ, b) = qⱼ means that when in state qᵢ given input b the automaton A will move to state qⱼ in one step. We extend the function δ to a mapping δ* : Q × Σ* → Q defined inductively by δ*(q, λ) = q and δ*(q, b₁, ..., bₙ₊₁) = δ(δ*(q, b₁, ..., bₙ), bₙ₊₁). The language L(A) accepted by A is the set of all strings α ∈ Σ* such that δ*(q₀, α) ∈ F. As is well known,
a language $L \subseteq \Sigma^*$ is accepted by a DFA if and only if, $L$ is regular, i.e. $L$ can be defined by a regular grammar. A state $q \in Q$ is said to be live if for some string $\alpha \in \Sigma^*$, $\delta^*(q, \alpha) \in F$, otherwise $q$ is said to be dead. Given a distinguished dead state $d_0$ we define string concatenation modulo the dead state $d_0$, $f : \Sigma^* \cup \{d_0\} \times \Sigma \rightarrow \Sigma^* \cup \{d_0\}$, by $f(d_0, \sigma) = d_0$ and $f(\alpha, \sigma) = \alpha \cdot \sigma$ for $\alpha \in \Sigma^*$. This function is used for automaton learning in Section 3. Given any DFA $A$ there exists a unique minimum state DFA $A'$ such that $L(A) = L(A')$ and this automaton is termed the canonical DFA for $L(A)$. A canonical DFA has at most one dead state.

### 2.2 The ID Algorithm

Our $IDS$ algorithm is an incremental version of the ID learning algorithm for DFA introduced in [Angluin 1981]. The ID algorithm is an online learning algorithm for DFA that starts from a given live complete set $P \subseteq \Sigma^*$ of queries about the target automaton, and generates new queries until a state space partition can be constructed. Since the algorithmic ideas and proof of correctness of $IDS$ are based upon those of ID itself, it is useful to review the ID algorithm here. Algorithm 1 presents the ID algorithm. Since this algorithm has been discussed at length in [Angluin 1981], our own presentation can be brief. A detailed proof of the correctness of ID and an analysis of its complexity can be found in [Angluin 1981].

A finite set $P \subseteq \Sigma^*$ of input strings is said to be live complete for a DFA $A$ if for every live state $q \in Q$ there exists a string $\alpha \in P$ such that $\delta^*(q_0, \alpha) = q$. Given a live complete set $P$ for a target automaton $A$, the essential idea of the ID algorithm is to first construct the set $T' = P \cup \{(\alpha, b) | (\alpha, b) \in P \times \Sigma\} \cup \{d_0\}$ of all one element extensions of strings in $P$ as a set of state names for the hypothesis automaton. The symbol $d_0$ is added as a name for the canonical dead state. This set of state names is then iteratively partitioned into sets $E_i(\alpha) \subseteq T'$ for $i = 0, 1, \ldots$ such that elements $\alpha, \beta$ of $T'$ that denote the same state in $A$ will occur in the same partition set, i.e. $E_i(\alpha) = E_i(\beta)$. This partition refinement can be proven to terminate and the resulting collection of sets forms a congruence on $T'$. Finally the ID algorithm constructs the hypothesis automaton as the resulting quotient automaton. The method used to refine the partition set is to iteratively construct a set $V$ of distinguishing strings, such that no two distinct states of $A$ have the same behaviour on all of $V$.

We will present the ID and $IDS$ algorithms so that similar variables share the same names. This pedagogic device emphasises similarity in the behaviour of both algorithms. However, there are also important differences in behaviour. Thus, when analysing the behavioural properties of program variables we will carefully distinguish their context as e.g. $v_n^{ID}$, $E_n^{ID}(\alpha)$, $\ldots$, and $v_n^{IDS}$, $E_n^{IDS}(\alpha)$, $\ldots$, etc. Our proof of correctness for $IDS$ will show how the learning behaviour of $IDS$ on a sequence of input strings $s_1, \ldots s_n \in \Sigma^*$ can be simulated by the behaviour of ID on the corresponding set of inputs $\{s_1, \ldots s_n\}$. Once this is established, one can apply the known correctness of ID to establish the correctness of $IDS$. The IID algorithm of [Parekh et al. 1998] also presents a simulation
Algorithm 1 ID Learning Algorithm

**Input:** A live complete set $P \subseteq \Sigma^*$ and a teacher DFA $A$ to answer membership queries $\alpha \in L(A)$?

**Output:** A DFA $M$ equivalent to the target DFA $A$.

1. begin
2. //Perform Initialization
3. $i = 0$, $v_0 = \lambda$, $V = \{v_i\}$,
4. $P' = P \cup \{d_0\}$, $T = P \cup \{f(\alpha, b) | (\alpha, b) \in P \times \Sigma\}$, $T' = T \cup \{d_0\}$
5. Construct function $E_0$ for $v_0 = \lambda$,
6. $E_0(d_0) = \emptyset$
7. $\forall \alpha \in T$
8. pose the membership query “$\alpha \in L(A)$?”
9. if the teacher’s response is yes
10. then $E_0(\alpha) = \{\lambda\}$
11. else $E_0(\alpha) = \emptyset$
12. end if
13. }
14. //Refine the partition of the set $T'$
15. while ($\exists \alpha, \beta \in P'$ and $b \in \Sigma$ such that $E_i(\alpha) = E_i(\beta)$ but $E_i(\alpha, b) \neq E_i(\beta, b)$)
16. do
17. Let $\gamma \in E_i(\alpha, b) \oplus E_i(\beta, b)$
18. $v_{i+1} = b\gamma$
19. $V = V \cup \{v_{i+1}\}$, $i = i + 1$
20. $\forall \alpha \in T_k$ pose the membership query ”$\alpha v_i \in L(A)$?”
21. }
22. if the teacher’s response is yes
23. then $E_i(\alpha) = E_{i-1}(\alpha) \cup \{v_i\}$
24. else $E_i(\alpha) = E_{i-1}(\alpha)$
25. end if
26. }
27. end while
28. //Construct the representation $M$ of the target DFA $A$.
29. The states of $M$ are the sets $E_i(\alpha)$, where $\alpha \in T$
30. The initial state $q_0$ is the set $E_i(\lambda)$
31. The accepting states are the sets $E_i(\alpha)$ where $\alpha \in T$ and $\lambda \in E_i(\alpha)$
32. The transitions of $M$ are defined as follows:
33. $\forall \alpha \in P'$
34. if $E_i(\alpha) = \emptyset$
35. then add self loops on the state $E_i(\alpha)$ for all $b \in \Sigma$
36. else $\forall b \in \Sigma$ set the transition $\delta(E_i(\alpha), b) = E_i(f(\alpha, b))$
37. end if
38. end.
method for ID. However, it is easily shown that IID does not satisfy Proposition 3.2 or Simulation Theorem 3.4 below, and thus the two algorithms have different behaviour. The behavioural properties of ID that are needed to complete this correctness proof can be stated as follows.

2.1. Theorem.
(i) Let \( P \subseteq \Sigma^* \) be a live complete set for a target DFA \( A \) containing \( \lambda \). Then given \( P \) and \( A \) as input, the ID algorithm terminates and the automaton \( M \) returned by ID is the canonical automaton for \( L(A) \).
(ii) Let \( l \in \mathbb{N} \) be the maximum value of program variable \( i^{ID} \) given \( P \) and \( A \). For all \( 0 \leq n \leq l \) and for all \( \alpha \in T \),

\[
E_n^{ID}(\alpha) = \{ v_j^{ID} \mid 0 \leq j \leq n, \; \alpha v_j^{ID} \in L(A) \}.
\]

(ii) By induction on \( n \).

**Basis.** Suppose \( n = 0 \). Then \( v_0^{ID} = \lambda \). For any \( \alpha \in T \), if \( \alpha v_0^{ID} \in L(A) \) then \( \alpha \in L(A) \) so \( E_0^{ID}(\alpha) = \{ v_0^{ID} \} \). If \( \alpha v_0^{ID} \not\in L(A) \) then \( \alpha \not\in L(A) \) so \( E_0^{ID}(\alpha) = \emptyset \). Thus \( E_0^{ID}(\alpha) = \{ v_j^{ID} \mid 0 \leq j \leq 0, \; \alpha v_j^{ID} \in L(A) \} \).

**Induction Step.** Suppose \( l \geq n > 0 \). Consider any \( \alpha, \beta \in P' \) and \( b \in \Sigma \) such that \( E_{n-1}^{ID}(\alpha) = E_{n-1}^{ID}(\beta) \) but \( E_n^{ID}(\alpha(b, b)) \neq E_n^{ID}(\beta(b, b)) \). Since \( n - 1 < l \) then \( \alpha, \beta \) and \( b \) exist. Then

\[
E_n^{ID}(\alpha(b, b)) \oplus E_n^{ID}(\beta(b, b)) \neq 0.
\]

Consider any \( \gamma \in E_{n-1}^{ID}(\alpha(b, b)) \oplus E_{n-1}^{ID}(\beta(b, b)) \) and let \( v_n^{ID} = b\gamma \). For any \( \alpha \in T \), if \( \alpha v_n^{ID} \in L(A) \) then \( E_n^{ID}(\alpha) = E_{n-1}^{ID}(\alpha) \cup \{ v_n^{ID} \} \) and if \( \alpha v_n^{ID} \not\in L(A) \) then \( E_n^{ID}(\alpha) = E_{n-1}^{ID}(\alpha) \). So by the induction hypothesis \( E_n^{ID}(\alpha) = \{ v_j^{ID} \mid 0 \leq j \leq n, \; \alpha v_j^{ID} \in L(A) \} \).

3 Correctness of the IDS Algorithm

In this section we present our IDS incremental learning algorithm for DFA. In fact, we consider two versions of this algorithm, with and without prefix closure of the set of input strings. We then give a rigorous proof that both algorithms correctly learn an unknown DFA in the limit in the sense of [Gold 1967]

In Algorithm 2 we present the main IDS algorithm, and in Algorithms 3 and 4 we give its auxiliary algorithms for iterative partition refinement and automaton construction respectively.

The version of the IDS algorithm which appears in Algorithm 2 we term the prefix free IDS algorithm, due to lines 22 and 25. Notice that lines 23 and 26 of Algorithm 2 have been commented out. When these latter two lines are uncommented and instead lines 22 and 25 are commented out, we obtain a version of the IDS algorithm that we term prefix closed IDS. We will prove that both prefix closed and prefix free IDS learn correctly in the limit. However, in Section 4 we will show that they have quite different performance characteristics with respect to computation time and query types.
Algorithm 2 IDS Learning Algorithm

Input: A file \( S = s_1, \ldots, s_l \) of input strings \( s_i \in \Sigma^* \) and a teacher DFA \( A \) to answer membership queries \( \alpha \in L(A) \)?

Output: A sequence of DFA \( M_t \) for \( t = 0, \ldots, l \) as well as the total number of membership queries and book keeping queries asked by the learner.

1. \( \text{begin} \)
2. \( \quad /\!\!/\text{Perform Initialization} \)

12. end if
13. }
14. end while

Algorithm 4 Automata Construction

1. The states of \(M_t\) are the sets \(E_i(α)\), where \(α \in T_k\)
2. The initial state \(q_0\) is the set \(E_i(λ)\)
3. The accepting states are the sets \(E_i(λ)\) where \(α \in T_k\) and \(λ \in E_i(α)\)
4. The transitions of \(M_t\) are defined as follows:
5. \(∀α \in P_k'\)
6. if \(E_i(α) = \emptyset\)
7. then add self loops on the state \(E_i(α)\) for all \(b ∈ Σ\)
8. else \(∀b ∈ Σ\) set the transition \(δ(E_i(α), b) = E_i(f(α, b))\)
9. end if
10. \(∀β \in T_k − P_k'\)
11. if \(∀α \in P_k' E_i(β) ≠ E_i(α)\) and \(E_i(β) ≠ \emptyset\)
12. then \(∀b ∈ Σ\) set the transition \(δ(E_i(β), b) = \emptyset\)
13. end if
We will prove the correctness of the prefix free IDS algorithm first, since this proof is somewhat simpler, while the essential proof principles can also be applied to verify the prefix closed IDS algorithm. We begin an analysis of the correctness of prefix free IDS by confirming that the construction of hypothesis automata carried out by Algorithm 4 is well defined.

3.1. Proposition. For each \( t \geq 0 \) the hypothesis automaton \( M_t \) constructed by the automaton construction Algorithm 4 after \( t \) input strings have been observed is a well defined DFA.

Proof. We need to show that \( M_t \) is a well defined DFA \( < \Sigma, Q, F, q_0, \delta > \). The input alphabet \( \Sigma \) for \( M_t \) is the same as the input alphabet for the target \( A \). The state set \( Q \) is represented by the sets \( E_i(\alpha) \), where \( \alpha \in T_k \). The accepting state set \( F \) consists of all sets \( E_i(\alpha) \), where \( \lambda \in E_i(\alpha) \). By definition, \( q_0 = E_i(\lambda) \) and since \( P_k \neq \emptyset \) then \( \lambda \in T_k \).

Finally for \( \delta \) to be well defined function \( \delta : \Sigma \times Q \rightarrow Q \) it must be uniquely defined for every state \( E_i(\alpha) \), where \( \alpha \in T_k \). So consider any \( \alpha \in T_k \). By lines 8 and 12 of Algorithm 4, \( \delta(E_i(\alpha), b) \) is defined for every \( b \in \Sigma \). We need to show that \( \delta(E_i(\alpha), b) \) is uniquely defined. So suppose \( E_i(\alpha) = E_i(\beta) \), we must show that \( \delta(E_i(\alpha), b) = \delta(E_i(\beta), b) \) for any \( b \in \Sigma \).

(i) Suppose \( \alpha \in P_k^t \) and \( \beta \in P_k^t \) then by lines 1 to 12 of Algorithm 3, \( E_i(f(\alpha, b)) = E_i(f(\beta, b)) \) for all \( b \in \Sigma \). Therefore by line 8 of Algorithm 4, \( \delta(E_i(\alpha), b) = \delta(E_i(\beta), b) \).

(ii) Suppose \( \alpha \in T_k - P_k^t \) and \( \beta \in P_k^t \) If \( E_i(\alpha) = E_i(\beta) \) then \( \delta(E_i(\alpha), b) \) is already uniquely defined by (i) above.

(iii) Suppose \( \alpha \in T_k - P_k^t \) and \( E_i(\alpha) \neq E_i(\beta) \) for any \( \beta \in P_k^t \) then by line 12 in Algorithm 4, \( \delta(E_i(\alpha), b) = \emptyset \), so the transition is defined. To show that it is uniquely defined consider any \( \beta \in T_k - P_k^t \) such that \( E_i(\alpha) = E_i(\beta) \). Then again by line 12 of Algorithm 4, \( \delta(E_i(\beta), b) = \emptyset = \delta(E_i(\alpha), b) \).

Hence the hypothesis automaton \( M_t \) is a well defined DFA.

Proposition 3.1 establishes that Algorithm 2 will generate a sequence of well defined DFA. However, to show that this algorithm learns correctly, we must prove that this sequence of automata converges to the target automaton \( A \) given sufficient information about \( A \). It will suffice to show that the behaviour of prefix free IDS can be simulated by the behaviour of ID, since ID is known to learn correctly given a live complete set of input strings (c.f. Theorem 2.1.(i)).

The first step in this proof is to show that the sequences of sets of state names \( P_k^{IDS} \) and \( T_k^{IDS} \) generated by prefix free IDS converge to the sets \( P^{ID} \) and \( T^{ID} \) of ID.

3.2. Proposition. Let \( S = s_1, \ldots, s_l \) be any non-empty sequence of input strings \( s_i \in \Sigma^* \) for prefix free IDS and let \( P^{ID} = \{ \lambda, s_1, \ldots, s_l \} \) be the corresponding input set for ID.

(i) For all \( 0 \leq k \leq l \), \( P_k^{IDS} = \{ \lambda, s_1, \ldots, s_k \} \subseteq P^{ID} \).

(ii) For all \( 0 \leq k \leq l \), \( T_k^{IDS} = P_k^{IDS} \cup \{ f(\alpha, b) \mid \alpha \in P_k^{IDS}, b \in \Sigma \} \subseteq T^{ID} \).

(iii) \( P_l^{IDS} = P^{ID} \) and \( T_l^{IDS} = T^{ID} \).
Proof. Clearly (iii) follows from (i) and (ii). We prove (i) and (ii) by induction on $k$.

**Basis.** Suppose $k = 0$. (i) $P_0^{IDS} = \{ \lambda \} \subseteq P^{ID}$. (ii) $T_0^{IDS} = \{ \lambda \} \cup \Sigma \subseteq T^{ID}$.

**Induction Step.** Suppose $k > 0$. (i) By the induction hypothesis $P_k^{IDS} = \{ \lambda, s_1, \ldots, s_{k-1} \} \subseteq P^{ID}$. So clearly $P_k^{IDS} = P_{k-1}^{IDS} \cup \{ s_k \} = \{ \lambda, s_1, \ldots, s_k \} \subseteq P^{ID}$.

(ii) By Definition

$$T_k^{IDS} = T_{k-1}^{IDS} \cup \{ s_k \} \cup \{ f(\alpha, b) \mid \alpha \in P_k^{IDS} - P_{k-1}^{IDS}, b \in \Sigma \}$$

$$= P_{k-1}^{IDS} \cup \{ s_k \} \cup \{ f(\alpha, b) \mid \alpha \in P_k^{IDS} - P_{k-1}^{IDS}, b \in \Sigma \}$$

$$\cup \{ f(\alpha, b) \mid \alpha \in P_{k-1}^{IDS}, b \in \Sigma \}$$

by the induction hypothesis (ii)

$$= P_k^{IDS} \cup \{ f(\alpha, b) \mid \alpha \in P_k^{IDS}, b \in \Sigma \}.$$

Next we turn our attention to proving some fundamental loop invariants for Algorithm 2. Since this algorithm in turn calls the partition refinement Algorithm 3 then we have in effect a doubly nested loop structure to analyse. Clearly the two indexing counters $k^{IDS}$ and $i^{IDS}$ (in the outer and inner loops respectively) both increase on each iteration. However, the relationship between these two variables is not easily defined. Nevertheless, since both variables increase from an initial value of zero, we can assume the existence of a monotone re-indexing function that captures their relationship.

**3.3. Definition.** Let $S = s_1, \ldots, s_l$ be any non-empty sequence of strings $s_i \in \Sigma^*$. The re-indexing function $K^S : \mathbb{N} \to \mathbb{N}$ for prefix free $IDS$ on input $S$ is the unique monotonically increasing function such that for each $n \in \mathbb{N}$, $K^S(n)$ is the least integer $m$ such that program variable $k^{IDS}$ has value $m$ while the program variable $i^{IDS}$ has value $n$. Thus, for example, $K^S(0) = 0$. When $S$ is clear from the context, we may write $K$ for $K^S$.

With the help of such re-indexing functions we can express important invariant properties of the key program variables $v_j^{IDS}$ and $E_n^{IDS}(\alpha)$, and via Proposition 3.2 their relationship to $v_j^{ID}$ and $E_n^{ID}(\alpha)$. Corresponding to the doubly nested loop structure of Algorithm 2, the proof of Simulation Theorem 3.4 below makes use of a doubly nested induction argument.

**3.4. Simulation Theorem.** Let $S = s_1, \ldots, s_l$ be any non-empty sequence of strings $s_i \in \Sigma^*$. For any execution of prefix free $IDS$ on $S$ there exists an execution of $ID$ on $\{ \lambda, s_1, \ldots, s_l \}$ such that for all $m \geq 0$:

(i) For all $n \geq 0$ if $K(n) = m$ then:

(a) for all $0 \leq j \leq n$, $v_j^{IDS} = v_j^{ID}$,

(b) for all $0 \leq j < n$, $v_n^{IDS} \neq v_j^{IDS}$,
(c) for all $\alpha \in T^\text{IDS}_m$, $E^\text{IDS}_n(\alpha) = \{ v^\text{IDS}_j | 0 \leq j \leq n, \ \alpha v^\text{IDS}_j \in L(A) \}$.  

(ii) If $m > 0$ then let $p \in \mathbb{N}$ be the greatest integer such that $K(p) = m - 1$.  
Then for all $\alpha \in T^\text{IDS}_m$, $E^\text{IDS}_p(\alpha) = \{ v^\text{IDS}_j | 0 \leq j \leq p, \ \alpha v^\text{IDS}_j \in L(A) \}$.  

(iii) The $m$th partition refinement of $\text{IDS}$ terminates.

Proof. By induction on $m$.  

basis. Suppose $m = 0$.  
(i) We prove the result by subinduction on $n$.

sub-basis. Suppose $n = 0$. Then $K(n) = m$.

(i.a) For ID and $\text{IDS}$, $v^0_0 = \lambda = v^0_0$.

(i.b) Holds vacuously since $n = 0$.

(i.c) Clearly $T^\text{IDS}_0 = \{ \lambda \} \cup \Sigma$. Consider any $\alpha \in T^\text{IDS}_0$. If $\alpha v^\text{IDS}_0 \in L(A)$ then $\alpha \in L(A)$ and $E^\text{IDS}_0(\alpha) = \{ v^\text{IDS}_0 \}$. If $\alpha v^\text{IDS}_0 \notin L(A)$ then $\alpha \notin L(A)$ and $E^\text{IDS}_0(\alpha) = \emptyset$. So

$$E^\text{IDS}_0(\alpha) = \{ v^\text{IDS}_j | 0 \leq j \leq n, \ \alpha v^\text{IDS}_j \in L(A) \}.$$  

sub-induction step. Suppose $n > 0$ and $K(n) = m$.

(i.a) Consider any $\alpha, \beta \in P^\text{IDS}_n$ and $b \in \Sigma$ such that $E^\text{IDS}_{n-1}(\alpha) = E^\text{IDS}_{n-1}(\beta)$ but $E^\text{IDS}_{n-1}(f(\alpha, b)) \neq E^\text{IDS}_{n-1}(f(\beta, b))$.

By Proposition 3.2.(i) $\alpha, \beta \in P^\text{IDS}_n$, so by the sub-induction hypotheses (i.a) and (i.c) and Theorem 2.1.(ii) (since $K(n-1) = m = 0$), $E^\text{IDS}_{n-1}(\alpha) = E^\text{IDS}_{n-1}(\beta)$ but $E^\text{IDS}_{n-1}(f(\alpha, b)) \neq E^\text{IDS}_{n-1}(f(\beta, b))$. Also

$$E^\text{IDS}_{n-1}(f(\alpha, b)) \oplus E^\text{IDS}_{n-1}(f(\beta, b)) = E^\text{IDS}_{n-1}(f(\alpha, b)) \oplus E^\text{IDS}_{n-1}(f(\beta, b)) \neq \emptyset.$$  

Let $\gamma \in E^\text{IDS}_{n-1}(f(\alpha, b)) \oplus E^\text{IDS}_{n-1}(f(\beta, b))$, then we can choose the same $\alpha, \beta, b$ and $\gamma$ for an execution of ID so that $v^\text{IDS}_j = v^\text{ID}_j = b\gamma$. So by the sub-induction hypothesis (i.a) for all $0 \leq j \leq n$, $v^\text{IDS}_j = v^\text{ID}_j$.

(i.b) For $\alpha, \beta, b$ and $\gamma$ as in (i.a) above either

$$\gamma \in E^\text{IDS}_{n-1}(f(\alpha, b)) \text{ and } \gamma \notin E^\text{IDS}_{n-1}(f(\beta, b)) \quad (1)$$  

or

$$\gamma \notin E^\text{IDS}_{n-1}(f(\alpha, b)) \text{ and } \gamma \in E^\text{IDS}_{n-1}(f(\beta, b)) \quad (2).$$  

Suppose (1) holds. Then $\gamma \in E^\text{IDS}_{n-1}(f(\alpha, b))$. So by the sub-induction hypothesis (i.c) for some $0 \leq x \leq n$, $\gamma = v^\text{IDS}_x$. Thus $v^\text{IDS}_n = b\gamma = v^\text{IDS}_x$. Suppose for a contradiction that for some $0 \leq y < n$, $v^\text{IDS}_y = v^\text{ID}_y$. Since $\alpha v^\text{IDS}_x \in L(A)$ then

$$v^\text{IDS}_y = b v^\text{IDS}_x \in E^\text{IDS}_{n-1}(\alpha) \quad (3),$$  

by sub-induction hypothesis (i.c). But by (1), $\gamma \notin E^\text{IDS}_{n-1}(f(\beta, b))$ so $v^\text{IDS}_y \notin E^\text{IDS}_{n-1}(f(\beta, b))$ hence $b v^\text{IDS}_x \notin L(A)$ by sub-induction hypothesis (i.c). Thus $\beta v^\text{IDS}_y \notin L(A)$. So by sub-induction hypothesis (i.c),

$$v^\text{IDS}_y \notin E^\text{IDS}_{n-1}(\beta) \quad (4).$$
So by (3) and (4) \(E^{IDS}_{n-1}(\alpha) \neq E^{IDS}_{n-1}(\beta)\). But this contradicts \(E^{IDS}_{n-1}(\alpha) = E^{IDS}_{n-1}(\beta)\).

By symmetry, if (2) holds a contradiction also arises. Thus for all \(0 \leq j < n, v^{IDS}_j \neq v^{IDS}_n\).

(i.c) Consider any \(\alpha \in T^{IDS}_0\). If \(\alpha v^{IDS}_n \in L(A)\) then \(E^{IDS}_n(\alpha) = E^{IDS}_{n-1}(\alpha) \cup \{v^{IDS}_n\}\) and if \(\alpha v^{IDS}_n \notin L(A)\) then \(E^{IDS}_n(\alpha) = E^{IDS}_{n-1}(\alpha)\). So by the sub-induction hypothesis (i.c) since \(K(n-1) = 0\) then

\[
E^{IDS}_n(\alpha) = \{v^{IDS}_j \mid 0 \leq j \leq n, \alpha v^{IDS}_j \in L(A)\}.
\]

This completes the sub-induction proof of (i).

(ii) Holds trivially since \(m \neq 0\).

(iii) Consider the 0-th refinement step in IDS. Clearly \(P^{IDS}_0\) is finite. For any \(\alpha, \beta \in P^{IDS}_0\) and \(b \in \Sigma\) and \(n \in \mathbb{N}\) such that \(K(n) = 0\) and \(E^{IDS}_{n-1}(\alpha) = E^{IDS}_{n-1}(\beta)\) but \(E^{IDS}_{n-1}(f(\alpha, b)) \neq E^{IDS}_{n-1}(f(\beta, b))\), then

\[
E^{IDS}_{n-1}(f(\alpha, b)) \oplus E^{IDS}_{n-1}(f(\beta, b)) \neq \emptyset.
\]

So considering any \(\gamma \in E^{IDS}_{n-1}(f(\alpha, b)) \oplus E^{IDS}_{n-1}(f(\beta, b))\) either

\[
\gamma \in E^{IDS}_{n-1}(f(\alpha, b)) \text{ and } \gamma \notin E^{IDS}_{n-1}(f(\beta, b)) \quad (5)
\]

or

\[
\gamma \notin E^{IDS}_{n-1}(f(\alpha, b)) \text{ and } \gamma \in E^{IDS}_{n-1}(f(\beta, b)) \quad (6).
\]

Let

\[
v^{IDS}_n = b\gamma \quad (7).
\]

Suppose (5) holds. If \(\alpha v^{IDS}_n \in L(A)\) then by (7) \(\alpha b\gamma \in L(A)\) and \(E^{IDS}_n(\alpha) = E^{IDS}_{n-1}(\alpha) \cup \{v^{IDS}_n\}\). But by (5) \(\gamma \notin E^{IDS}_{n-1}(f(\beta, b))\) so \(\beta b\gamma \notin L(A)\). So \(E^{IDS}_n(\beta) = E^{IDS}_{n-1}(\beta)\). By (i.b) and (i.c) \(v^{IDS}_n \notin E^{IDS}_{n-1}(\alpha)\). So

\[
E^{IDS}_n(\beta) = E^{IDS}_{n-1}(\beta) = E^{IDS}_{n-1}(\alpha) \neq E^{IDS}_n(\alpha).
\]

By symmetry, the same result follows if (6) holds. Therefore on each iteration of the 0-th partition refinement loop, the number of such triples \(\alpha, \beta\) and \(b\) strictly decreases. So the 0-th partition refinement loop must terminate.

**Induction Step.** Suppose \(m > 0\).

(i) We prove the result by sub-induction on \(n\).

**Sub-basis.** Suppose \(n = 0\). Then \(K(n) \neq m\) so the result holds trivially.

**Sub-induction Step.** Suppose \(n > 0\) and \(K(n) = m\).

(i.a) Suppose that \(n\) is the least integer such that \(K(n) = m\), i.e. \(K(n-1) = m-1\). Consider any \(\alpha, \beta \in P^{IDS}_m\) and \(b \in \Sigma\) such that \(E^{IDS}_{n-1}(\alpha) = E^{IDS}_{n-1}(\beta)\) but \(E^{IDS}_{n-1}(f(\alpha, b)) \neq E^{IDS}_{n-1}(f(\beta, b))\). By Proposition 3.2.(i) \(\alpha, \beta \in P^{IDS}_m\) so by the
induction hypotheses (ii), (i.a) and Theorem 2.1.(ii), \( E_{n-1}^{ID}(\alpha) = E_{n-1}^{ID}(\beta) \) but
\( E_{n-1}^{ID}(f(\alpha, b)) \neq E_{n-1}^{ID}(f(\beta, b)) \). Furthermore
\[
E_{n-1}^{IDS}(f(\alpha, b) \oplus E_{n-1}^{IDS}(f(\beta, b)) = E_{n-1}^{IDS}(f(\alpha, b)) \oplus E_{n-1}^{IDS}(f(\beta, b)) \neq \emptyset.
\]
Let \( \gamma \in E_{n-1}^{IDS}(f(\alpha, b) \oplus E_{n-1}^{IDS}(f(\beta, b)) \) then we can choose the same \( \alpha, \beta, b \) and
\( \gamma \) for an execution of ID so that
\[
v_n^{IDS} = b\gamma = v_n^{ID}.
\]
By the sub-induction hypothesis (i.a) for all \( 0 \leq j \leq n, v_j^{IDS} = v_j^{ID} \).
Suppose that \( n \) is strictly greater than the least integer such that \( K(n) = m \),
i.e. \( K(n - 1) = m \). The proof is similar to above, but we use sub-induction hypothesis (i.a)
instead of induction hypothesis (ii).
(i.b) The proof is similar to the proof of (i.b) in the subinduction step of the
induction basis.
(i.c) For \( \alpha, \beta, b \) and \( \gamma \) as in (i.a) above, suppose that \( n \) is the least integer such
that \( K(n) = m \), i.e. \( K(n - 1) = m - 1 \).
Consider any \( \alpha \in T_m^{IDS} \). If \( \alpha v_n^{IDS} \in L(A) \) then
\( E_n^{IDS}(\alpha) = E_{n-1}^{IDS}(\alpha) \cup \{ v_n^{IDS} \} \), and if \( \alpha v_n^{IDS} \notin L(A) \) then
\( E_n^{IDS}(\alpha) = E_{n-1}^{IDS}(\alpha) \). So by the induction hypothesis (ii)
\[
E_n^{IDS}(\alpha) = \{ v_j^{IDS} \mid 0 \leq j \leq n, \alpha v_j^{IDS} \in L(A) \}.
\]
Suppose that \( n \) is greater than least integer such that \( K(n) = m \), i.e. \( K(n - 1) = m \). The proof is similar to above but we use sub-induction hypothesis (i.c)
instead of induction hypothesis (ii).
This completes the sub-induction proof of (i).
(ii) Let \( p \in \mathbb{N} \) be the greatest integer such that \( K(p) = m - 1 \). By the induction hypothesis
(i.b) for all \( \alpha \in T_{m-1}^{IDS} \)
\[
E_p^{IDS}(\alpha) = \{ v_j^{IDS} \mid 0 \leq j \leq p, \alpha v_j^{IDS} \in L(A) \}.
\]
and by line 3 of IDS Algorithm 2, for all \( \alpha \in T_m^{IDS} - T_{m-1}^{IDS} \),
\[
E_p^{IDS}(\alpha) = \{ v_j^{IDS} \mid 0 \leq j \leq p, \alpha v_j^{IDS} \in L(A) \}.
\]
So for all \( \alpha \in T_m^{IDS} \)
\[
E_p^{IDS}(\alpha) = \{ v_j^{IDS} \mid 0 \leq j \leq p, \alpha v_j^{IDS} \in L(A) \}.
\]
(iii) Consider the \( m \)-th refinement step in prefix free IDS. The proof is similar
to the proof of (iii) in the subinduction step of the induction basis.

Notice that in the statement of Theorem 3.4 above, since both ID and IDS
are non-deterministic algorithms (due to the non-deterministic choice on line
17 of Algorithm 1 and line 3 of Algorithm 3), then we can only talk about the
existence of some correct simulation. Clearly there are also simulations of $IDS$ by ID which are not correct, but this does not affect the basic correctness argument.

**3.5. Corollary.** Let $S = s_1, \ldots, s_l$ be any non-empty sequence of strings $s_i \in \Sigma^*$. Any execution of prefix free $IDS$ on $S$ terminates with the program variable $k^{IDS}$ having value $l$.

**Proof.** Follows from Simulation Theorem 3.4.(iii) since clearly the while loop of Algorithm 2 terminates when the input sequence $S$ is empty.

Using the detailed analysis of the invariant properties of the program variables $B_k^{IDS}$ and $T_k^{IDS}$ in Proposition 3.2 and $v_3^{IDS}$ and $E_i^{IDS}(\alpha)$ in Simulation Theorem 3.4 it is now a simple matter to establish correctness of learning for the prefix free $IDS$ Algorithm.

**3.6. Correctness Theorem.** Let $S = s_1, \ldots, s_l$ be any non-empty sequence of strings $s_i \in \Sigma^*$ such that $\{ \lambda, s_1, \ldots, s_l \}$ is a live complete set for a target DFA $A$. Then prefix free $IDS$ terminates on $S$ and the hypothesis automaton $M_1^{IDS}$ is a canonical representation of $A$.

**Proof.** By Corollary 3.5, prefix free $IDS$ terminates on $S$ with the variable $k^{IDS}$ having value $l$. By Simulation Theorem 3.4.(i) and Theorem 2.1.(ii), there exists an execution of ID on $\{ \lambda, s_1, \ldots, s_l \}$ such that $E_n^{IDS}(\alpha) = E_0^{IDS}(\alpha)$ for all $\alpha \in T_1^{IDS}$ and any $n$ such that $K(n) = l$. By Proposition 3.2.(iii), $T_1^{IDS} = T^{IDS}$ and $P_l^{IDS} = P^{IDS}$. So letting $M^{IDS}$ be the canonical representation of $A$ constructed by ID using $\{ \lambda, s_1, \ldots, s_l \}$ then $M^{IDS}$ and $M_1^{IDS}$ have the same state sets, initial states, accepting states and transitions.

Our next result confirms that the hypothesis automaton $M_1^{IDS}$ generated after $t$ input strings have been read is consistent with all currently known observations about the target automaton. This is quite straightforward in the light of Simulation Theorem 3.4.

**3.7. Compatibility Theorem.** Let $S = s_1, \ldots, s_l$ be any non-empty sequence of strings $s_i \in \Sigma^*$. For each $0 \leq t \leq l$ and each string $s \in \{ \lambda, s_1, \ldots, s_l \}$, the hypothesis automaton $M_t^{IDS}$ accepts $s$ if, and only if the target $A$ does.

**Proof.** By definition, $M_1^{IDS}$ is compatible with $A$ on $\{ \lambda, s_1, \ldots, s_l \}$ if, and only if, for each $0 \leq j \leq t$, $s_j \in L(A) \Leftrightarrow \lambda \in E_i^{IDS}(s_j)$, where $i_t$ is the greatest integer such that $K(i_t) = t$ and the sets $E_i^{IDS}(\alpha)$ for $\alpha \in T_1^{IDS}$ are the states of $M_1^{IDS}$. Now $v_0^{IDS} = \lambda$. So by Simulation Theorem 3.4.(i).(c), if $s_j \in L(A)$ then $s_jv_0^{IDS} \in L(A)$ so $v_0^{IDS} \in E_i^{IDS}(s_j)$, i.e. $\lambda \in E_i^{IDS}(s_j)$, and if $s_j \notin L(A)$ then $s_jv_0^{IDS} \notin L(A)$ so $v_0^{IDS} \notin E_i^{IDS}(s_j)$, i.e. $\lambda \notin E_i^{IDS}(s_j)$.

Let us briefly consider the correctness of prefix closed $IDS$. We begin by observing that the non-sequential ID Algorithm 1 does not compute any prefix closure of input strings. Therefore, Proposition 3.2 does not hold for prefix closed $IDS$. In order to obtain a simulation between prefix closed $IDS$ and ID we modify Proposition 3.2 to the following.
3.8. Proposition. Let $S = s_1, \ldots, s_l$ be any non-empty sequence of input strings $s_i \in \Sigma^*$ for prefix closed IDS and let $P^{ID} = \text{Pref}\{\lambda, s_1, \ldots, s_l\}$ be the corresponding input set for ID.

(i) For all $0 \leq k \leq l$, $P^{IDS}_k = \text{Pref}\{\lambda, s_1, \ldots, s_k\} \subseteq P^{ID}$.
(ii) For all $0 \leq k \leq l$, $T^{IDS}_k = P^{IDS}_k \cup \{f(\alpha, b) \mid \alpha \in P^{IDS}_k, b \in \Sigma\} \subseteq T^{ID}$.
(iii) $P^{IDS}_l = P^{ID}$ and $T^{IDS}_l = T^{ID}$.

Proof. Similar to the proof of Proposition 3.2.

We leave it to the reader, as an exercise, to make similar changes to Simulation Theorem 3.4 and Corollary 3.5, with the help of which one can establish the correctness of prefix closed IDS.

3.9. Correctness Theorem. Let $S = s_1, \ldots, s_l$ be any non-empty sequence of strings $s_i \in \Sigma^*$ such that $\{\lambda, s_1, \ldots, s_l\}$ is a live complete set for a target DFA $A$. Then prefix closed IDS terminates on $S$ and the hypothesis automaton $M^{IDS}_l$ is a canonical representation of $A$.

Proof. Exercise, following the proof of Theorem 3.6.

4 Empirical Performance Analysis

Little seems to have been published about the empirical performance and average time complexity of incremental learning algorithms for DFA in the literature. By the average time complexity of the algorithm we mean the average number of queries needed to completely learn a DFA of a given state space size. This question can be answered experimentally by randomly generating a large number of DFA with a given state space size, and randomly generating a sequence of query strings for each such DFA.

From the point of view of software engineering applications such as testing and model inference, we have found that it is important to distinguish between the two types of queries about the target automaton that are used by IDS during the learning procedure. On the one hand the algorithm uses internally generated queries (we call these book-keeping queries) and on the other hand it uses queries that are supplied externally by the input file (we call these membership queries). From a software engineering applications viewpoint it seems important that the ratio of book-keeping to membership queries should be low. This allows membership queries to have the maximum influence in steering the learning process externally. The average query complexity of the IDS algorithm with respect to the numbers of book-keeping and membership queries needed for complete learning can also be measured by random generation of DFA and query strings.

To measure each query type, Algorithm 2 has been instrumented with two integer variables $bquery$ and $mquery$ intended to track the total number of each type of query used during learning (lines 8, 20 and 32).

Since two variants of the IDS algorithm were identified, with and without prefix closure of input strings, it was interesting to compare the performance of each of these two variants according to the above two average complexity measures.
4.1 Experimental Procedure

To empirically measure the average time and query complexity of our two \textit{IDS} algorithms, two experiments were set up. These measured:

1. the average computation time needed to learn a randomly generated DFA (of a given state space size) using randomly generated membership queries, and
2. the total number of membership and book-keeping queries needed to learn a randomly generated DFA (of a given state space size) using randomly generated membership queries.

We chose randomly generated DFA with state space sizes varying between 5 and 50 states, and an equiprobable distribution of transitions between states. No filtering was applied to remove dead states, so the average effective state space size was therefore somewhat smaller than the nominal state space size.

\begin{figure}[h]
\centering
\includegraphics[width=0.6\textwidth]{evaluation_framework.png}
\caption{Evaluation Framework}
\end{figure}

The experimental setup consisted of the following components:
1. a random input string generator,
2. a random DFA generator,
3. an instance of the \textit{IDS} Algorithm (prefix free or prefix closed),
4. an automaton equivalence checker.

The architecture of our evaluation framework and the flow of data between these components are illustrated in Figure 1.

The purpose of the equivalence checker was to terminate the learning procedure as soon as the hypothesis automaton sequence had successfully converged.
to the target automaton. There are several well known equivalence checking algorithms described in literature. These have runtime complexity ranging from quadratic to nearly linear execution times. We chose an algorithm with nearly linear time performance described in [Norton 2009]. This was to minimise the overhead of equivalence checking in the overall computation time. The IDS algorithms and the entire evaluation framework were implemented in Java. The performance of the input string and DFA generators is dependent on Java’s Random class which generates pseudorandom numbers that depend upon a specific seed. To minimize the chance of generating the same pseudo random strings/automata again the seed was set to the system clock.

![Fig. 2. Average Time Complexity](image)

### 4.2 Results and Interpretation

The two graphs in Figure 2 illustrate the outcome of our experiments to measure the average time and average query complexity of both IDS algorithms, as described in Section 4.1.

Figure 2.A presents the results of estimating the average learning time for the prefix free and prefix closed IDS algorithms as a function of the state space size of the target DFA. For large state space sizes $n$, the data sets of randomly generated target DFA represent only a small fraction of all possible such DFA of size $n$. Therefore the two data curves are not smooth for large state space sizes. Nevertheless, there is sufficient data to identify some clear trends. The average learning time for prefix free IDS learning is substantially greater than corresponding time for prefix closed IDS, and this discrepancy increases with state space size. The reason would appear to be that prefix free IDS throws away data about the target DFA that must be regenerated randomly (since
input string queries are generated at random). The average time complexity for prefix free $IDS$ learning seems to grow approximately quadratically, while the average time complexity for prefix closed $IDS$ learning appears to grow almost linearly within the given data range. From this viewpoint, prefix-closed $IDS$ appears to be the superior algorithm.

Figure 2.B presents the results of estimating the average number of membership queries and book-keeping queries as a function of the state space size of the target DFA. Again, we have compared prefix-closed with prefix free $IDS$ learning. Allowance must also be made for the small data set sizes for large state space values. We can see that membership queries grow approximately linearly with the increase in state space size, while book-keeping queries grow approximately quadratically, at least within the data ranges that we considered. There appears to be a small but significant decrease in the number of both book-keeping and membership queries used by the prefix-closed $IDS$ algorithm. The reason for this appears to be similar to the issues identified for average time complexity. Prefix closure seems to be an efficient way to gather data about the target DFA. From the viewpoint of software engineering applications discussed in Section 1, now prefix free $IDS$ appears to be preferable. This is because the decreasing ratio of book-keeping to membership queries improves the possibility to direct the learning process using externally generated queries (e.g. from a model checker).

5 Conclusions

We have presented two versions of the $IDS$ algorithm which is an incremental algorithm for learning DFA in polynomial time. We have given a rigorous proof that both algorithms correctly learn in the limit. Finally we have presented the results of an empirical study of the average time and query complexity of $IDS$. These empirical results suggest that $IDS$ is well suited to applications in software engineering, where an incremental approach that allows externally generated online queries is needed. This conclusion is further supported in [Meinke and Sindhu 2011], where we have evaluated the $IDS$ algorithm for learning based testing of reactive systems, and shown that it leads to error discovery up to 4000 times faster than using non-incremental learning.
