Flexible simple-pole expansion of distribution functions

T. Löfgren and H. Gunell

Abstract

A method for parameterization and expansion of distribution functions is presented. The expansion has a finite number of simple poles, which gives efficient numerical calculations and control of all converging moments. The low velocity region is Maxwell-like and the high velocity tail follows an inverse power law. The method is applied to Maxwell-like distributions with and without suppressed tails. Dispersion relations can be obtained for a wide class of distributions, using building blocks available in any numerical library. Dispersion relations, for ordinary Langmuir waves and for beam-plasma interactions with intermediate temperature and beam to plasma density ratio, are derived. The Landau damping obtained in the long wavelength regime, is smaller than for the generalized Lorentzian distributions, for a given degree in the power law.
1 Introduction

In collisionless plasmas in space as well as in the laboratory, the electron distribution function \( f(r, v) \) is often found to be non-Maxwellian. Loss cones and electrostatic sheaths (in e.g. a plasma diode) can cut the distribution for higher velocities. In natural space and astrophysical plasmas the distribution function often follows an inverse power law in the high energy tail \( f \propto v^{-\alpha} \). There is a need for simple, flexible, distributions that more accurately describe those physical situations. It should be possible to increase or suppress the distribution in some velocity regions, and to cover plasmas in equilibrium states, the Maxwellian distribution should be a special case.

The description in this paper will be one dimensional, but the ideas are easily generalized to two or three dimensions. The Maxwellian distribution with its analytical continuation is numerically and theoretically problematic due to the essential singularity at infinity. The resonance distribution (or Lorentzian) \( f_L \propto \left[1 + v^2/(2v_r^2)\right]^{-1} \) gives simple calculations but it has large tails and infinite energy [1]. The multiplicity of the poles in the kappa-distribution (or generalized Lorentzian) \( f_K \propto \left[1 + v^2/(2\kappa v_r^2)\right]^{-1+\kappa} \) [2] introduces computational difficulties. Using distribution functions with simple poles, the distribution function can be changed considerably without changing the numerical codes. It will be straightforward to include any filter characteristics from analog filters reducing or increasing desired part of the distribution.

This paper describes a method of expanding the Maxwellian distribution, that gives converging moments to any specified order with the tail following an inverse power law. All poles of this expansion are simple which gives short coded computations. Once the poles have been found it is cheap to calculate the converging moments and thus to normalize the distribution. A cut can be introduced in the tails by a mask that is multiplied with the ordinary expansion. The mask will be a max-flat filter, and the Butterworth filter [3] will serve as an example. The final, normalized, expansion will be used to derive dispersion relations, for electrostatic linear waves in homogeneous Vlasov-plasmas, in one and multi component systems.

2 Expansion of the distribution function

The plasma is assumed to be homogeneous and collisionless with an ion background of infinite mass. The electron distribution function \( f \) is Maxwell-like for moderate velocities but it is possible to introduce a cutoff at higher velocities. In a dimensionless (and not yet normalized) description, \( f \) can be written as a product

\[
f(x) = M_w(x)T(x) \quad x \equiv (v - v_d)/v_t \tag{1}
\]

where \( M_w \) is a low-velocity (hence warm) expansion of the Maxwellian \( f_0 = e^{-\frac{x^2}{2}} \) and \( T \) is a Butterworth mask with critical velocity \( x_0 \). \( v_d \) is the average drift and \( v_t \) is the standard deviation of the true Maxwellian. Note that this, \( v_t \), is not the exact measure corresponding to the mean energy for distributions
Figure 1: (a) The Maxwellian $f_0$ (dashed) and the expansions $M_w$ for $m = 1, \ldots, 10$ (solid). (b) The Butterworth mask for $n = 1, \ldots, 10$.

with truncated or thick tails. Taylor expanding $1/e^{x^2}$ the two factors read

\[
\begin{align*}
M_w(x) &= \left[1 + \frac{e^2}{2} + \ldots + \frac{1}{m!}\left(\frac{e^2}{2}\right)^m\right]^{-1} \\
T(x) &= \left[1 + (\frac{x}{x_0})^{2n}\right]^{-1}
\end{align*}
\]

(2)

The expansion $M_w$, displayed in fig. 1a, is a generalization of the resonance distribution which corresponds to the special case $m = 1$. The filter parameter $n$ should be chosen to get the desired sharpness of the cutoff as shown in fig. 1b. Totally $m + n$ must be chosen high enough to get convergence of the desired moments and to suppress the distribution to required velocity, depending on the application. This sum could also be chosen to match an inverse power law since $f \propto x^{-(2m + 2n)}$ as $x \to \infty$. If the distribution is chosen to approximate the Maxwellian distribution $f_0$, i.e., without cutoff ($n = 0$), it is necessary to check the validity of the Taylor expansion. The neglected terms in the full expansion are small (compared to 1) and fast decaying if $m! > (\frac{e^2}{2})^m$.

Using the asymptotic behavior of the gamma function the condition becomes $|x|_{\text{max}} \sim \sqrt{m}$ for large $m$. The radius of convergence is thus asymptotically comparable to the kappa distribution which has $|x| < \sqrt{\kappa}$ [2]. In the modeling of evanescent wave modes, the errors in the full complex plane are important. The error in the Taylor expansion, of $f_0$, in the complex plane is displayed in fig. 2. The analytical continuation of $f_0$ is an entire function but $M_w$ has poles in the finite complex plane. The absolute errors will however be small for all real $x$.

The poles of $T$ which are analytically known $(x_0 e^{\frac{3p-1}{2n}i\pi}, \ p = 1, \ldots, 2n)$, and of $M_w$ found by standard numerical packages as, e.g. MATLAB, are in general simple. Factorization and decomposition of $f$ into partial fractions
Figure 2: The relative (a,b) and absolute errors (c,d) in the $m = 8$ expansion of $f_0 = e^{-x^2}$, with the poles $b_i$ as stars. The contours are the powers of ten. The figures are based on a not normalized expansion. The lower limit of the errors are due to finite numerical resolution in the computations.

result in an expression of the form

$$f = \sum_{i=1}^{2m+2n} \frac{a_i}{x - b_i}.$$  \hspace{1cm} (3)

When $m$, $n$ are chosen, the residues $a_i$ and poles $b_i$ are calculated once and for all and $f$ is normalized by dividing the residues with the zeroth moment. If the moment $\langle x^q \rangle = \int_{-\infty}^{\infty} f(x)x^q dx$ does converge, it is possible to close the contour
Figure 3: The relative (a,b) and absolute errors (c,d) in the normalized $m = 8$ expansion of $f_0 = e^{-x^2}$, with the poles $b_l$ as stars. The contours are the powers of ten. The expansion is normalized to $\sqrt{2\pi}$ (not 1) with the residue sum, $f = \sqrt{2\pi} \left[ 2\pi i \sum_{b_l \in U} a_l \right]^{-1} M_{\nu}(f_0)$, to make the absolute errors comparable with those in fig. 2. The broader tails of $M_{\nu}$ along the real axis give a reduction of the distribution function in the low-velocity region. The transition from overestimation to underestimation is seen as a wavy pattern in (b) and as islands in (d).

in the upper half plane, $U$, enclosing half of the poles, and get

$$\langle v^q \rangle = 2\pi i \sum_{b_l \in U} a_l b_l^q \quad q < 2m + 2n - 1.$$  \hspace{1cm} (4)
Table 1: Moments $\langle x^q \rangle$ of the normalized distribution. The moments are related to the known Maxwellian moments which are given by $(q-1)!!$. The table entries are $(x^q)/(q-1)!!$.

The moments $\langle x^q \rangle$ of the normalized Maxwellian expansions $(n = 0, m)$ are compared with the known even Maxwellian moments, given by $(q-1)!!$, in tab. 1. The average energy is well described by $v_t$ using only a few terms. With $2m$ slightly higher than the highest required moment the "blow-up" of the highest moments is avoided. With the normalization of the expansion additional deviations from the Maxwellian distribution are introduced, see fig. 3. The tails of $M_w$ are broader than for the Maxwellian distribution which gives a reduction of the distribution function for low velocities.

The simple pole expansions in eq. 3 can formally be used as a parameterization in a wide class of applications. The specific numbers $(\alpha_i, \beta_i)$ need not to be used until the final numerical computations.

### 3 Dispersion relations

The dispersion relation in a one-component system, which will serve as an example, only defines one time and one length scale from the plasma frequency $\omega_p$ and the thermal velocity $v_t$. There is thus perfect scaling as long as the rest frame of a one component system is considered. For programming purposes the dimensionless variables are preferably kept, but for clarity in the derivation of the dispersion relations below variables with correct dimensions are reintroduced. The new variables will be marked with a tilde. The normalized distribution function is $\tilde{f} = \sum_\nu \frac{\tilde{a}_i}{\nu - \tilde{b}_i}$ with

$$\begin{align*}
\tilde{a}_i &= a_i \left[ 2\pi i \sum_{b_i \in U} a_i \right]^{-1}, \\
\tilde{b}_i &= b_i \nu_t + \nu_d
\end{align*}$$

where the residues and poles come from eq. 3. The corresponding normalized Maxwellian is $\tilde{f}_0 = \frac{1}{\nu p \sqrt{2\pi}} e^{-\frac{\nu^2}{2\nu^2}}$.

Dispersion relations will be studied in a linear, homogeneous, Vlasov-Poisson picture. The first order perturbation is of the form $e^{i(\omega t - kz)}$ (i.e.,
\( \Im(\omega) < 0 \) for growing modes) and the phase velocity is, by the Landau prescription [4], assumed to be in the lower half plane when deriving the dispersion relation. Accordingly, the integration contour can be closed in the upper half plane without enclosing the phase velocity pole, resulting in

\[
1 = \omega_p^2 \int_{-\infty}^{\infty} \frac{\tilde{f} dv}{(\omega - kv)^2} = \omega_p^2 2\pi i \sum_{\tilde{b}_i \in U} \frac{\tilde{a}_i}{(\omega - k\tilde{b}_i)^2}.
\]  

(6)

No solution exists at the poles \( \omega - k\tilde{b}_i = 0 \), for finite wavelength, and the dispersion relation can be written as a polynomial in \( \frac{\omega}{k} \) for a given \( k \neq 0 \).

\[
\prod_i \left( \frac{\omega}{k} - \tilde{b}_i \right)^2 - \frac{\omega_p^2}{k^2} 2\pi i \sum_i \tilde{a}_i \prod_{j \neq i} \left( \frac{\omega}{k} - \tilde{b}_j \right)^2 = 0
\]

(7)

where the notation \( \tilde{b}_i, \tilde{b}_j \in U \), i.e., restriction to the upper half plane, has been omitted in the summation and the products. Polynomial root finders in standard numerical packages can find the \( 2(m+n) \) roots. The roots are sorted to get \( 2(m+n) \) continuous wave modes \( \xi(k) \), see fig. 4.

In general \( \tilde{f} \) can be used to model non-Maxwellian distributions. First the errors introduced by using \( \tilde{f}, (n = 0) \), approximating a true Maxwellian distribution, are discussed. There are two error types, denoted E1 and E2, introduced in the integration in eq. 6. The open contour along the real axis with the phase velocity pole below the contour is considered.

**E1** Along the Cauchy principal integral at the real axis, an error is introduced in the averaging process. If the weight \( \omega_p^2(\omega - kv)^{-2} \) is a slowly varying function for real \( v \), it is sufficient to require small absolute errors in \( f \) to avoid this error since the major contribution to the integral in eq. 6 comes from the central part of the distribution. Then a small absolute error can be achieved with a few terms \( (m) \) for all phase velocities \( (\Re(\omega/k)) \) (figs. 2 and 3). But if \( \omega/k \) is close to the real axis the local error contribution must be small compared to the contributions to the integral near \( v = 0 \), i.e., \( \left| \left[ \tilde{f}(\Re(\xi/k)) \right] - \left[ \tilde{f}_0(\Re(\xi/k)) \right] / \Im(\omega)^2 \right| \ll \left| \tilde{f}(0)/\omega^2 \right| \). The error is negligible if \( \Re(\omega/k) < v_t \sqrt{2(m!)}^{1/2m} \).

**E2** The integration contour encircles the phase velocity pole (clockwise) if \( \Im(\omega/k) > 0 \). The residue \( \frac{\partial f}{\partial \omega}(\omega/k) \) is well described in the same regions as \( \tilde{f} \) in figs. 2 and 3. Close to \( \tilde{b}_i \), the expansion diverge and nonsensical results are expected. In contrast to E1, E2 only affects the upper half plane and the E2 error is most important if the damping is large.

Analytical solutions to eq. 7 can be obtained in the two limits \( k \to 0 \) and \( k \to \infty \). The Maxwellian approximation \( n = 0, m \neq 0, v_{td} = 0 \) will be examined as an example, but any normalized distribution that can be expressed as a simple pole expansion can be treated in the same way.

In the limit \( k \to \infty \) the second term in eq. 7 vanishes and a double root at each \( \tilde{b}_i \) remains. By numbering the poles, different wave modes can be separated. The poles from \( M_w \) are artificial and a strong E2 error is introduced.
Figure 4: Dispersion roots in complex phase velocity space with $k \in [2^{-5}, 2^4] \omega_p / v_t$ as parameter for the expansions $n = 0$ and $m = 6$ (solid) and $m = 5$ (dashed). The poles, $b_i$, are marked with circles and the limiting solutions $k \to 0$ ($v_{ph,r}^0$ in eq. 12) are marked with stars. The Langmuir roots are only slightly modified, between the two expansions, for $\Im(\omega/k) < 1.3v_t$, but there is a large deviation close to the poles, where the waves are strongly damped. The correspondence between some $b_i$ and some $v_{ph,r}^0$ is a general property of the Maxwellian expansion, that disappears if the distribution is modified ($n > 0$). The authors have no explanation of this result. The poles will always be symmetric around the imaginary axis ($v_d = 0$), and purely imaginary poles are found for odd $m$.

close to the poles. The poles from $T$ are not artificial since they represent a physical cutoff in the distribution. With $\Im(\omega) = k\Im(b_i) \to \infty$, no solution in this regime is interesting, since they are strongly damped. By the numerical solution in fig. 5, it is seen that the approximation is acceptable for all reasonable dampings (and $m > 4$). Note that all solutions (for all distributions) are damped for wavelengths short enough.

In the limit $k \to 0$, the roots $\omega = O(1)$ are found by expanding the denominator in the sum of eq. 6 in the limit $k/\omega \to 0$

$$\omega^2 = \omega_p^2 2\pi i \sum_{b_i \in U} \left[ \tilde{a}_i \sum_{j=0}^{\infty} (j + 1) \left( \frac{k b_i}{\omega} \right)^j \right] =$$

$$\omega_p^2 \sum_{j=0}^{2m-2} (j + 1) \left( \frac{k}{\omega} \right)^j \langle u^j \rangle +$$

$$\omega_p^2 2\pi i \sum_{b_i \in U} \left[ \tilde{a}_i \sum_{j=2m-1}^{\infty} (j + 1) \left( \frac{k b_i}{\omega} \right)^j \right]$$

where the last equality follows from the converging moments in eq. 4. Note
Figure 5: The positive $\Re(\omega)$ Langmuir root for expansions $n = 0$ and $m \in \{2, \ldots, 10\}$. The upper panels (a-c) concern the real part and the lower panels (d-f) the imaginary part. The highest $m$ solution is shown in (a,d). The difference in the solution $\Re(\omega(m) - \omega(m = 10))/\omega_p$ and $\Im(\omega(m) - \omega(m = 10))/\omega_p$ is presented in (b,e) respectively. The real part is practically independent on $m$ for $m > 4$. The absolute error in $\Re(\omega(m))$ is small but the relative error in the damping rate is large for low values of $k$. $P$ in (c) is the function that makes $\omega = \omega_p \left( 1 + \frac{3}{2} \omega_p^{-2} k^2 \omega_p^2 (1 + P(k)) \right)$ an exact statement. If $P \ll 1$ the second moment is well described and if $k \partial P/\partial k \ll 1$, the curveform is quadratic. $Q$ in (f) shows the behavior of the Landau damping, $Q = \frac{\Im(\omega)}{\omega_p} = (2m-1)$. The solutions in (d-f) with $\Im(\omega/\omega_p) < 10^{-14}$ have been omitted because of large numerical noise.

that since there is a finite number of converging moments, it is not possible to interchange the integration and the limit $k/\omega \to 0$ in eq. 6. The two Langmuir roots, $\omega = O(1)$, are found by using that $f$ is normalized $(2\pi i \sum \tilde{a}_i = 1)$, i.e., $\omega = \pm \omega_p + O(k)$. Let $\omega_q(k) = \omega_p + \delta_1 + \ldots + \delta_q$ be the solution to the order $k^q$. Keep terms to $k^2$ in eq. 8 and multiply with $\omega_q^2$

\[
(\omega_{q-1} + \delta_q)^{q+2} + O(k^{q+1}) = \omega_p^2 2\pi i \sum_{b_i \in U} \tilde{a}_i \sum_{j=0}^{q} (j+1)(kb_i)^j(\omega_{q-1} + \delta_q)^{q-j}
\]  

(9)

The solution to $O(k^q)$ is

\[
(\omega_{q-1})^{q+2} + (q+2)\omega_{q-1}^{q+1}\delta_q + O(k^{q+1}) = q\omega_p^q + (q+2)\omega_{q-1}^{q+1} +
\]

\[
\omega_p^2 2\pi i \sum_{b_i \in U} \tilde{a}_i \sum_{j=0}^{q} (j+1)(kb_i)^j(\omega_{q-1})^{q-j}
\]

(10)
where one of the \( j = 0 \) terms is moved out of the summations. This linear equation in \( \delta_q \) gives
\[
\delta_q = \frac{1}{2} \omega_p 2\pi i \sum_{b_i \in U} \tilde{a}_i \left( \frac{k b_i}{\omega_p} \right)^q + O(k^{q+1}) + \frac{1}{2} \omega_p^{-q} \sum_{b_i \in U} \left[ \tilde{a}_i \sum_{j=0}^{q-1} (j+1)(k b_i)^j (\omega_{q-1})^{q-1-j} \right] - (\omega_{q-1})^{q+1} \]  
(11)

The first term is the contribution from the extra \( k^q \) term in eq. 8. The last terms seem to include lower order corrections, but by replacing \( q \) by \( q - 1 \) in eq. 9 it is clear that these terms are a first correction to the error made in the previous step, and thus \( O(k^q) \). The higher order terms should be removed out of this sum. To save some tedious bookkeeping this step is formally included in the additional term \( O(k^{q+1}) \).

The terms \( 2\pi i \sum \tilde{a}_i \tilde{b}_i^q \) are in general complex numbers. But to all orders \( q \) of converging moments \( \langle v^q \rangle = 2\pi i \sum \tilde{a}_i \tilde{b}_i^q \in \mathbb{R} \) and thus the corrections \( \delta_q \) are real. The Landau damping will come from the first non-converging moment, i.e., \( \Im(\omega) \sim O(k^{2m-1}) \). In the limit \( m \to \infty \), the damping is of infinite order which is well known for Maxwellian distributions, but for all finite \( m \) the damping is overestimated due to the broader tails. Both E1 and E2 errors contribute. The increased damping rate in the high phase velocity region has also been reported for the generalized Lorentzian distribution [5].

The generalized Lorentzian has an asymptotic damping rate \( \Im(\omega) \sim O(k^{2\kappa-1}) \) with asymptotic distribution function \( f_{\kappa} \propto v^{-2(\kappa+1)} \) where \( \kappa \) is the spectral index [6]. The \( M_{\kappa} \) expansion thus has a smaller (or more Maxwell-like) Landau damping than the generalized Lorentzian for given degree of the high velocity power law. The degree of the power law does thus not uniquely define the asymptotic degree of the damping rate in the long wavelength regime.

As a first example of eq. 11, the resonance distribution \( (m = 1) \) gives \( \delta_1 = 2\pi i k b = i \sqrt{2} k v_t \), which in fact is the exact solution [1]. The second example is a distribution with converging energy \( (m \geq 2) \). The first order correction vanishes for a symmetric distribution and the second order correction \( \delta_2 = \frac{3}{2} \omega_p^{-1} k^2 \langle v^2 \rangle \) gives the Bohm-Gross dispersion relation \( \omega = \omega_p \left( 1 + \frac{3}{2} \omega_p^{-2} k^2 \langle v^2 \rangle \right) \). In this limit the real part gives the same result as for the Maxwellian distributions and as for the generalized Lorentzian [6]. The apparent deviation in the second moment in tab. 1 only implies that the thermal velocity \( v_t \), as defined in this paper, does not exactly represent the standard deviation of the distribution function \( f \).

The Langmuir roots from numerically calculated dispersion relations are presented in fig. 5 for different expansions \( m \). The real part is almost independent of \( m \) when \( \Im(\omega) < \omega_p \) and \( m > 4 \), but the relative error in \( \Im(\omega) \) is important for low values of \( k \). The behavior of the solutions in the low \( k \) limit, i.e., the quadratic real part and the damping rate of the order \( O(k^{2m-1}) \), is numerically confirmed.

The remaining roots, in the limit \( k \to 0 \), are \( O(k) \) and they are found as
zeros to the second term in eq. 7, i.e., \( \omega = k v_{p,h,r}^0 + O(k^2) \), where \( v_{p,h,r}^0 \) solves

\[
\sum_i \tilde{a}_i \prod_{j \neq i} \left( v_{p,h,r}^0 - \bar{b}_j \right)^2 = 0 \quad (\bar{b}_j \in U).
\]

(12)

The zeros \( v_{p,h,r}^0 \) will always be in the upper half plane for one component expansions of the type \( M_w T \), since these are stable by the Penrose condition.

In a system which can be described by a collection of components \( (l) \), with different drifts \( (v_{d,l}) \), temperatures \( (v_{t,l}, (x_{0,l})) \), densities \( (\omega_{p,l}^2) \) and expansions \( (m_i, n_i) \) the dispersion relation formally reads

\[
1 = 2\pi i \sum_l \left[ \frac{\omega_{p,l}^2 \sum_{l, i \in U} \frac{\tilde{a}_{i,l}}{(\omega - k \bar{b}_{i,l})^2}}{\omega_p^2} \right]
\]

(13)

where each component is normalized as \( 2\pi i \sum_i \tilde{a}_{i,l} = 1 \). What is said in this section is still valid since this also represents a simple pole expansion. All roots are strongly damped for short wavelengths, and the Langmuir roots still follow \( \omega = \pm \omega_p + O(k) \), where \( \omega_p^2 = \sum_l \omega_{p,l}^2 \). By performing the analysis for \( \delta_q \) in analogy with the one component system, the solution becomes \( \omega = \pm \omega_p + k \sum_i \frac{\omega_{p,i}^2}{\omega_p^2} v_{d,i} + O(k^2) \), i.e., Langmuir waves Doppler shifted by the weighted mean velocity. If all components \( (l) \) represent particles with the same mass \((\text{e.g. electrons})\), this is a centre of momentum Doppler shift. Some of the \( O(k) \) solutions may be growing in this multiple component system.

4 Beam-plasma example

The beam-plasma interaction will be used to show the usefulness of this parameterization technique for non-Maxwellian distributions with strong beams and intermediate temperatures, i.e., regions not reachable by ordinary limit solutions. Those parameter regions are common at \( \text{e.g.} \) the high potential side in double-layer experiments and in some beam plasma experiments \([7, 8]\). At a double layer the electron beam is accelerated in the potential well from the (warm) plasma. Since the double layer potential drop \( \phi_{DL} \) can be of the same order as \( \frac{ke T_c}{2} \), the contraction of the distribution in the acceleration phase is small, and a much broader distribution is achieved than in electron gun or cathode experiments. In mirror field configurations or at the boundaries in a plasma diode, the high energy tail is lost. Two distributions with parameters in tab. 2 will be examined. A stable distribution \((A1)\) is turned unstable \((A2)\) by an introduced cut in the tail. A low degree of the expansion parameters \( m, n \) is chosen to make the figures more readable.

The roots in complex phase velocity plane are shown in fig. 6. The marked waves span different phase velocity regions and the roots will be named from the behaviour in the long wavelength regime. The Langmuir roots will never intersect the Doppler shifted beam roots, and the roots are strongly perturbed. It is straightforward to use this method to study topological shifts as presented in O’Neil and Malmberg \([9]\). The shift from \( "\text{Dirac-delta beam}" \) as in the
Table 2: Parameters used in the beam-plasma examples. The total plasma frequency $\omega_p$ and the beam drift $v_d$ are used as scaling parameters. The background plasma has index $l = 1$ and the beam has $l = 2$. The difference between the two cases A1 and A2 is the introduced cut (in A2) at $v = v_t$ in the stationary distribution.

Figure 6: (a) The normalized distribution functions for parameters in tab. 2, A1 (solid) and A2 (dashed). (b) Dispersion roots in complex phase velocity space with $k \in [2^{-6}, 2^4]\omega_p/v_d$ as parameter for the distributions in (a). The poles, $b_i$, are marked with circles and the limiting solutions $k \to 0$ ($v_{ph,i}$, in eq. 12) are marked with stars. The poles are centred around the component drift velocities and the lowest lying poles only exist for the parameters according to A2 in table 2.

the presented result to "gentle bump" type solutions, i.e., when the forward Langmuir root (LW2) connects to a pole with $\Re(b_i) < v_d$, appears in strongly damped regions because of the broad distributions. For temperatures and expansions as in A1 (tab. 2) the mode shift is at $\omega_p^2 \approx 0.0036\omega_p^2$. The forward Langmuir root (LW2) is only slightly modified by the cut in the distribution, but the backward root (LW1) has a strongly reduced Landau damping. The slow space charge wave (SSCW) becomes unstable by the cut. This wave mode and LW1 connect to a new poles.

The three dispersion roots are presented in fig. 7. There is a clear asymmetry between the two Langmuir roots, and the negative root (LW1) has solutions above $-\omega_p$. In the low $k$ limit this is a result from the linear term in $k$ by the centre of momentum Doppler shift in the non-stationary distribution. For
shorter wavelengths this is due to the connection of the positive Langmuir root with a fast space charge wave (ω > ωp). The positive Langmuir root (LW2) is Landau damped by the thermal spread in the beam but the imaginary part of the negative root is (in this phase velocity region) determined by the background plasma. LW1 is thus more strongly damped (solid lines) and it is also more sensitive to the suppressed high velocity tail. The unstable bandwidth in the SSCW is ω ∈ [0, 1.3]ωp. Unstable solutions above ωp are a common feature with warm plasma components (ut ∼ ud) and it is not an effect of the suppressed tails.

If the expansion method is used to approximate a collection of Maxwellian distributions in temperature and density regions near those in tab. 2, some notes about the errors are appropriate. The growing part of the SSCW has a small E1 error, if Re(ω/k) is in this central part of the distributions, and a non-existent E2 error in the lower half plane. For clearly unstable solutions the errors are small. For marginally unstable systems it is hard to determine the points were ω/k crosses the real axis, especially if Re(ω/k) is more than a few thermal velocities from the components drift velocities ud,j. The other roots are strongly damped and in phase velocity regions where the parameterization method is rough.
5 Mapping of the distribution function in conservative fields

When a known velocity distribution changes under the influence of conservative forces, like e.g. electrostatic sheaths or magnetic mirror fields, it will prove useful to perform a mapping of the distribution function. By mapping the residues and poles, instead of recalculating the velocity distribution for each new position, the computational efforts can be reduced. This mapping also gives a better understanding of the introduced modifications.

Assume that the poles $\tilde{b}_i$ and residues $\tilde{a}_i$ of the distribution function $\tilde{f}(r, v) = \sum_{\nu} \frac{\tilde{a}_i(\phi(r))}{v - \tilde{b}_i(\phi(r))}$ are known in a point in space, say $r = 0$, where the potential energy is at minimum $\phi = 0$. The particles enters a region with a monotonic retarding potential $\phi(r)$, that approaches infinity for large $r$, i.e., an infinite mirror. Hence the distribution function at will be symmetric around $v = 0$. The total particle energy, $\frac{m_0^2}{2} + \phi$, is conserved and thus $\tilde{f}(r, v) = \tilde{f}(0, \pm \sqrt{v^2 + 2\phi(r)/m})$.

For all distribution functions that are symmetric around $v = 0$ the poles come in pairs so that for each pole $\tilde{b}_i(0)$ with residue $\tilde{a}_i(0)$ there is another pole $-\tilde{b}_i(0)$ whose residue is $-\tilde{a}_i(0)$. We here perform the calculation of the mapped poles and their residues for such a pair of poles. The part of the distribution function that is described by the considered pair is

$$f_p(0, v) = \frac{\tilde{a}_i(0)}{v - \tilde{b}_i(0)} - \frac{\tilde{a}_i(0)}{v + \tilde{b}_i(0)} = \frac{2\tilde{a}_i(0)\tilde{b}_i(0)}{v^2 - \tilde{b}_i^2(0)},$$

(14)

where $\Re\tilde{b}_i(0) > 0$. At $r \neq 0$, where $\phi > 0$ this becomes

$$f_p(r, v) = \frac{2\tilde{a}_i(0)\tilde{b}_i(0)}{v^2 + \frac{2\phi}{m} - \tilde{b}_i^2(0)} = \frac{2\tilde{a}_i(0)\tilde{b}_i(0)}{(v - \tilde{b}_i(\phi))(v + \tilde{b}_i(\phi))},$$

(15)

where $\tilde{b}_i(\phi) = \sqrt{\tilde{b}_i^2(0) - \frac{2\phi}{m}}$, and the square root function is chosen so that $\tilde{b}_i(\phi)$ is in the upper half plane. This can be rewritten as

$$f_p(r, v) = \frac{\tilde{a}_i(\phi)}{v - \tilde{b}_i(\phi)} - \frac{\tilde{a}_i(\phi)}{v + \tilde{b}_i(\phi)},$$

where

$$\begin{cases} 
\tilde{b}_i(\phi) = \sqrt{\tilde{b}_i^2(0) - \frac{2\phi}{m}} , \quad \Re\tilde{b}_i(\phi) > 0 \\
\tilde{a}_i(\phi) = \tilde{a}_i(0) \cdot \frac{\tilde{b}_i(0)}{\tilde{b}_i(\phi)} 
\end{cases}$$

(16)

It is useful to write the distribution function as a sum, $\tilde{f}(0, v) = \sum_{\tilde{b}_i(0) \in U} \frac{\tilde{a}_i(0)}{v - \tilde{b}_i(0)} - \frac{\tilde{a}_i(0)}{v + \tilde{b}_i(0)}$, over the poles in the upper half plane and map $\tilde{a}_i(0)$ and $\tilde{b}_i(0)$ according to eq. 16. When dispersion relations are calculated the lower half plane does not need to be considered at all.

In the case of a finite mirror, $\phi(r) < \infty$, particles with energies over a certain level are collected instead of reflected. This cutoff is introduced at that energy level through the use of a mask as described in section 2. Since the cut $T$ is a smooth function, and not a perfect cut, this must be seen as an approximation.

6 Summary

A flexible form for parameterization of distribution functions is presented. A low velocity expansion of Maxwellian distributions is combined with a cut in the tails represented by a Butterworth mask. With general filters and with a collection of components almost any distribution function can be described. The high velocity tail follows an inverse power law. The distribution is characterized by a vector of residues and simple poles. From the simple pole expansion it is cheap to calculate all converging moments and thus to normalize the distribution. The parameterization is used to derive linear dispersion relations. By this parameterization technique it is possible to study kinetic modifications in collisionless plasmas with non-Maxwellian distributions. It can also be used as an asymptotic Maxwellian expansion to get simple expressions that are easy to code. The expansion has small relative deviation from the Maxwellian for \( v < v_t\sqrt{2(mt)^{1/2m}} \), and small absolute error for all real velocities. In a wave picture all phase velocities in this region are well described if the Landau damping is not to strong. The Landau damping does not go fast enough to zero in the long wavelength regime but the real part is well described. The smallest errors are obtained for growing waves but again the imaginary part is uncertain close to the real phase velocity axis. Error estimates can be obtained by performing the calculations for different degrees of the expansion. More terms in the expansion gives higher converging moments, more strongly suppressed Landau damping and more Maxwell-like description in both the high and the low phase velocity region.

Abstract

A method for parameterization and expansion of distribution functions is presented. The expansion has a finite number of simple poles, which gives efficient numerical calculations and control of all converging moments. The low velocity region is Maxwell-like and the high velocity tail follows an inverse power law. The method is applied to Maxwell-like distributions with and without suppressed tails. Dispersion relations can be obtained for a wide class of distributions, using building blocks available in any numerical library. Dispersion relations, for ordinary Langmuir waves and for beam-plasma interactions with intermediate temperature and beam to plasma density ratio, are derived. The Landau damping obtained in the long wavelength regime, is smaller than for the generalized Lorentzian distributions, for a given degree in the power law.
